

Same principle as previous portfolio exercises.

First, I start with the baseline run:

For the second iteration, I decided to tweak the parameters of the GRU model

```
mirrow.set_tag('dev', your=...  
config = ModelConfig(  
    input_size=3,  
    hidden_size=64,  
    num_layers=1,  
    output_size=20,  
    dropout=0.1,  
)
```

original parameters

```

config = ModelConfig(
    input_size=3,
    hidden_size=128,
    num_layers=2,
    output_size=20,
    dropout=0.1,
)

```

adjusted parameters

This resulted in longer training, but also in....:

A way better accuracy score!

Next I increased hidden size even more and also dropout a bit to prevent overfitting.

This last run achieved an accuracy well above the mentioned goal in the script, so it seems like mission successful.
